

plan4res installation

version 1.2 June 13, 2024

1 Quick Install in a nutshell

Windows specific

See https://gitlab.com/cerl/plan4res/p4r-env#windows.

Requirements: Windows 7 Pro 64bit SP1 or higher and <u>PowerShell</u> 3.0 or higher / CPU must support <u>hardware virtualization</u>. (virtualization features may need to be enabled in the BIOS)

- Install Git for Windows (use default settings) https://git-for-windows.github.io/
- Install VirtualBox and Extension Pack https://www.virtualbox.org/wiki/Downloads GitHub openENTRANCE/plan4res-scripts: This repository contains add-ons tools for plan4res: data preprocessing, data formatting, data postprocessing, IAMC writer, visualisation
- Install Vagrant https://www.vagrantup.com/downloads.html
- (Optional) Install Vagrant Manager http://vagrantmanager.com/downloads/
- Run Git Bash.
- vagrant up # Start the Virtual Machine. First execution requires downloading the image..

To run the commands listed below, use Git Bash.

For all operating systems

Create empty directory (for example *install_dir*) where you want to install plan4res. It should not contain special characters or whitespaces!

We recommend using CPLEX as the solver. You must have a CPLEX linux installer available, such as cplex_studio2211.linux_x86_64.bin, referenced as *cplex_studioXXXXXX.bin* below.

- cd install_dir
- 2. git clone https://github.com/openENTRANCE/plan4res.git
- 3. git clone --recursive https://gitlab.com/cerl/plan4res/p4r-env.git
- 4. cd p4r-env
- 5. git config submodule.recurse true
- 6. If using openMPI for parallelization, edit config/plan4res.conf and change MPICH to OpenMPI
- 7. bin/p4r # downloads the image and executes the environment. This can take time!
- 8. exit
- 9. bin/p4r add-on stopt

Important note for Windows: $install_dir\p4r-env\scripts\add-ons\sms++$ must be edited by replacing, if necessary, the 3 instances of make $-j\$(getconf_NPROCESSORS_ONLN)$ by make -j1.../p

- 10. bin/p4r add-on sms++ CPLEX=cplex studioxxx.bin
- 11. cd scripts
- 12. mkdir python
- 13. cd python
- 14. git clone https://github.com/openENTRANCE/openentrance.git
- 15. git clone https://github.com/openENTRANCE/plan4res-scripts.git
- 16. cd ../../..
- 17. cp plan4res/LaunchScripts/run* p4r-env/
- 18. cp -r plan4res/LaunchScripts/include p4r-env/scripts/

You are now ready to run the model!

Chapter 2 provides an in-depth description of the plan4res environment (p4r-env). Chapter 3 provides the procedure for installing p4r-env and chapter 4 provides the procedure for installing the necessary software within p4r-env.

2 Description of the plan4res environment

The installation procedure is laid out in section 3Install p4r-env.

The p4r-env environment is a container (see <u>CERL / Plan4Res / p4r-env · GitLab</u>) that allows for a simple installation and use of all plan4res solvers and tools. Note that all components of plan4res can also run without this environment but it requires to install all dependencies manually, which can prove time-consuming and tricky.

The p4r-env environment can be installed on Linux, Windows, Mac and even CRAY machines. Once the environment is installed, the functional behavior will be the same on all kinds of systems. Computation time will depend on the computer's performance.

p4r-env is a singularity container, which means that it requires singularity to be installed.

Instructions to install are summarized in section 4 but you may look at detailed instructions here https://gitlab.com/cerl/plan4res/p4r-env/-/tree/master#p4r-environment-installation-execute-once Windows has some specific prerequisites, summarized at the beginning of section 1, which are detailed here https://gitlab.com/cerl/plan4res/p4r-env/-/tree/master#prerequisite

The other software installed in the environment to run plan4res are:

- **StOpt** (see <u>Stochastic Control / StOpt · GitLab</u>): a stochastic optimization library used for solving the Seasonal Storage Valuation (SSV) problem. See installation procedure in section 4.1.
- **SMS++** (see <u>SMS++</u> / <u>The SMS++</u> <u>Project · GitLab</u>): modelling and optimization library including the 3 main solvers of plan4res in the OM4A toolbox. See installation procedure in section 4.2.
- (Optional) A preprocessing tool p4r-env/scripts/python/plan4res-scripts/ CreateInputPlan4res.py: this tool allows to create plan4res dataset out of long-term pluriannual energy system scenarios (eg from GENeSYS-MOD).
- A formatting tool, p4r-env/scripts/python/plan4res-scripts/ format.py, (mandatory apart if you are creating the NetCDF input data files in the format required by SMS++ on your own); this tool creates input data file with the format required by SMS++ taking as inputs user friendly CSV and XLSX files.
- (Optional) **Postprocessing tool**: this tool transforms the files created by the solver (SMS++) into more user-friendly files and creates some synthetic results.
- (Optional) **IAMC format transformation**: this tool transforms the results from the postprocessing tool into files within the <u>IAMC</u> format, which can then be uploaded to the Scenario Explorer hosted at https://data.ece.iiasa.ac.at/openmod4africa.
- (Optional) Visualization tool: creates graphs. For OpenMod4Africa, the toolbox will include specific visualization tools that will work on the model output in the IAMC format, so you may skip this step.

See [D4.1]¹ for more details on the plan4res model.

¹ openMod4Africa *D4.1 Catalogue of models and their functionalities* for a description of the software and models.

p4r-env structure

At the end of the installation process, the p4r-env repository contains the following sub-repositories:

- bin/: contains all software executables. Added to the user PATH environment variable.
- config/: contains the p4r-env configuration files:
- data/: this repository will store all data and results. This repository contains 4 sub-repositories:
 - o cache/: for data cached from external sources.
 - local/: for storing user's data and case study specific settings and config files (SMS++ configuration files and settings for python scripts).
 - scratch/: used as working directory of tools and can be used for volatile data during program runs.
 - o staging/: for storing data that need to be uploaded to external repositories.
- scripts/: contains the necessary includes for the main workflow scripts (run*), which are executing different tasks repeatedly or sequentially, as well as the following sub-repositories:
 - o scripts/add-ons/ contains the scripts for installing stopt and sms++.
 - o scripts/python/ contains all python codes:
 - scripts/python/plan4res-scripts/ contains the preprocessing, formatting, postprocessing python scripts as well as their configuration files settings*.yaml.
 - scripts/python/openentrance/ contains the nomenclature python code.
- site/: used by p4r-env users to install their own local software

For conducting a case study, a user will have to create a repository for the case study within data/local (eg MyCaseStudy). All python configuration files (settings*.yaml from scripts/python/plan4res-scripts/ as well as all SMS++ configuration files from config/ shall be copied by the user in data/local/MyCaseStudy as those configuration files may be case study dependent.

Optional: using p4r-env shell

To launch the plan4res environment, go in the p4r-env repository and type bin/p4r (on Windows, use Git Bash to do so). This will start a shell in the plan4res containerized environment such as:

[P4R-ENV] /home/Plan4Res/P4Rtest/p4r-env >

In classical uses of plan4res, you will not need to work from the shell as scripts for running all different workflows are available which include launching the environment and all software.

3 Install p4r-env

3.1 Windows install

The procedure is available at https://gitlab.com/cerl/plan4res/p4r-env#windows. It is reproduced below with some more information.

Installation requires Windows 7 Pro 64bit SP1 or higher and <u>PowerShell</u> 3.0 or higher. Furthermore, the CPU must support <u>hardware virtualization</u>. On many systems, the hardware virtualization features first need to be enabled in the BIOS.

3.1.1 Required packages Installation (execute once)

- Install Git for Windows (use default settings) https://git-for-windows.github.io/
- Install VirtualBox and Extension Pack https://www.virtualbox.org/wiki/Downloads
- Install Vagrant https://www.vagrantup.com/downloads.html
- (Optional) Install Vagrant Manager http://vagrantmanager.com/downloads/

The goal of Vagrant and VirtualBox is to emulate a UNIX system on the Windows computer. Vagrant Manager provides a GUI to facilitate the management of the VM.

3.1.2 Installation

• Run Git Bash.

If working behind a proxy, define the following environment variables:

- export http_proxy = <proxy address>:<port>
- export https_proxy = \${http_proxy}

Then enter the following commands:

- git clone --recursive https://gitlab.com/cerl/plan4res/p4r-env
- cd p4r-env
- If you are using a platform which allows parallelization with OpenMPI, you need before the next step to edit the file config/plan4res.conf This file contains the following section:

- git config submodule.recurse true
- vagrant plugin install vagrant-proxyconf
- Choose the mount of memory /nb of CPU you wish to give to vagrant by editing the file p4r-env/Vagrantfile (see below)
- vagrant up # Starts the Virtual Machine. First execution requires downloading the image. See NOTE below for more details.

Proceed with the generic installation procedure below.

3.1.3 Vagrant settings

To avoid issues with memory fragmentation while using Vagrant, we advise to allocate at least 8 Gb of RAM if the computer can afford it. To so so, in file *Vagrantfile* located in *install_dir/p4r-env*, edit parameter vb.memory (in Mb):

You may also increase the number of CPUs allocated to the VM if possible, on your machine. In above example, it is set to 6.

3.2 Linux install

- Create a directory (eg install_dir)
- 2. Download p4r-env:

```
git clone --recursive <a href="https://gitlab.com/cerl/plan4res/p4r-env.git">https://gitlab.com/cerl/plan4res/p4r-env.git</a>
```

This will create the directory install dir /p4r-env

- 3. cd p4r-env
- 4. If you are using a platform which allows parallelization with OpenMPI, you need before the next step to edit the file config/plan4res.conf This file contains the following section:

5. bin/p4r

This will download the container

3.3 Updating the environment

To update the environment, use the following commands:

- 1. cd p4r-env
- 2. bin/p4r

hin/p4r downloads an updated Singularity Image File (SIF), whose size is very big which can take a long time.

In case you wish to avoid updating (and thus downloading a very big file) each time you run p4r-env, you can edit the config file: p4r-env/config/plan4res.conf by replacing P4R_SINGULARITY_IMAGE_PRESERVE=0 with P4R_SINGULARITY_IMAGE_PRESERVE=1 (or

4 Install software in p4r-env

uncommenting line P4R_SINGULARITY_IMAGE_PRESERVE=1).

The procedures presented in this section and sub-sections apply to all operating systems.

In order to run plan4res you need to install:

- StOpt
- SMS++ which will create the 3 executables for the CEM, SSV and UC models
- The python scripts:
 - Formatting tool
 - Preprocessing tool
 - Postprocessing tool

- Visualization tool
- IAMC writing tool

4.1 StOpt

StOpt must be installed before SMS++

1. If you had previously installed (even if it failed), remove StOpt and sms++:

```
bin/p4r add-on stopt uninstall
bin/p4r add-on sms++ uninstall
```

2. Install StOpt:

```
bin/p4r add-on stopt
```

4.2 SMS++

SMS++ uses its own solving libraries as well as external libraries for solving linear problems. It can use both CPLEX, GUROBI, SCIP, HIGHS, and COIN-OR.

Instructions for installation of these software can be found here https://gitlab.com/smspp/smspp-project/-/wikis/Installing-SMS++#sms

As an example, in case you are using CPLEX for solving optimization problems, you need to copy your <u>Linux</u> CPLEX installer file (cplex_studioxxx.bin) in the p4r_env directory and ensure your CPLEX license is valid.

3. Install SMS++:

```
bin/p4r add-on sms++ CPLEX=cplex_studioxxx.bin
```

See SMS++ / The SMS++ Project · GitLab for more information.

4.3 Python scripts

The python scripts need to be installed by the user in p4r-env/scripts/python (after creation of this repository):

```
cd p4r-env/scripts
mkdir python
cd python
```

• openENTRANCE nomenclature definitions:

This python package contains definitions of variables and regions, it is used by the other python scripts.

```
git clone https://github.com/openENTRANCE/openentrance.git
```

Python scripts for preprocessing, postprocessing, formatting, visualization and IAMC writing

```
git clone https://github.com/openENTRANCE/plan4res-scripts.git
```

This command will create the repository /scripts/python/plan4res-scripts which

² Even for Windows or Mac: the p4r-env environment uses a Linux Virtual Machine.

contains python scripts as well as their settings files: settings*.yaml, which should not be changed in this repository but will serve as templates. Those settings files settings*.yaml should be copied to each case study specific repository, e.g. /data/local/MyCaseStudy/settings/.

4.4 Get documentation, configuration files and launching scripts

• General workflow scripts

These are the scripts run*, which are part of the https://github.com/openENTRANCE/plan4res.git repository. These scripts are meant to be in p4r-env. The include subdirectory must be in p4r-env/scripts.

- o runSSV proceeds to the following steps:
 - Create netcdf files
 - Run sddp_solver (computes Bellman values for seasonal storages)
- o runSIM proceeds to the following steps:
 - Create netcdf files
 - Run sddp_solver (compute simulations)
 - Post-treat results, write IAMC files and create graphs
- o runCEM proceeds to the following steps:
 - Create netcdf files
 - Run investment_solver (compute best investment and run simulations)
 - Post-treat results, write IAMC files and create graphs
- In case the users wishes to conduct the workflow step-by-step, additional scripts are available:
 - runCREATE* creates the csv plan4res dataset
 - runFORMAT* creates the netcdf SMS++ input files
- o Full workflow scripts allow to run the different steps:
 - runSSVandSIM proceeds to the following steps:
 - Create plan4res csv input files
 - Create SMS++ netcdf input files for SSV
 - Run sddp_solver (computes Bellman values)
 - Creates SMS++ netcdf input files for simulation
 - Runs sddp_solver in simulation mode
 - Post-treat results, write IAMC and create graph
 - runSSVandCEM proceeds to the following steps:
 - Create plan4res csv input files
 - Create SMS++ netcdf input files for SSV
 - Run sddp_solver (computes Bellman values)
 - Creates SMS++ netcdf input files for capacity expansion
 - Runs investment solver
 - Post-Treat results, write IAMC and create graphs
- <u>SMS++ configuration files</u> are also in the https://github.com/openENTRANCE/plan4res.git repository. These are template files that should not be modified: As for settings*.yaml, they should be copied to each case study specific repository, eg. /data/local/MyCaseStudy/settings/

4.5 Updating StOpt and/or SMS++

For StOpt

If you need to update StOpt, you must uninstall **both** SMS++ and StOpt:

- bin/p4r add-on stopt uninstall
- bin/p4r add-on sms++ uninstall

And then reinstall both:

- bin/p4r add-on stopt
- bin/p4r add-on sms++ CPLEX=cplex_studioxxx.bin Indeed, StOpt must always be installed before SMS++.

For sms++

Uninstall then reinstall sms++:

- bin/p4r add-on sms++ uninstall
- bin/p4r add-on sms++ CPLEX=cplex studioxxx.bin

4.6 Update scripts and setting files

New versions of the scripts and setting files mentioned in sections 4.3 and 4.4 may be released.

The following directories can be updated:

- plan4res: to update the run scripts, the documentation and SMS++ configuration files.
- p4r-env/scripts/python/openentrance: to update the openENTRANCE nomenclature definition.
- p4r-env/scripts/python/plan4res-scripts: to update the Python scripts and settings.

To check if new versions are available, run the following commands:

- cd p4r-env/scripts/python/openentrance
- 2. git fetch --dry-run --verbose

If the following output is displayed, it means your installation is up to date:

```
$ git fetch --dry-run --verbose
POST git-upload-pack (196 bytes)
From https://github.com/openENTRANCE/openentrance
95b813e..aab1e9f main -> origin/main
= [up to date] devops/rename-repo -> origin/devops/rename-repo
```

Otherwise, you can perform the update using:

3. git pull

Do the same with repositories plan4res or p4r-env/scripts/python/plan4res-scripts if necessary.

After the update, as in the initial installation procedure (see section 1), you need to move files run* from plan4res/LaunchScripts to p4r-env, as well as directory plan4res/LaunchScripts/include to p4r-env/scripts and move the SMS++ configuration files to /data/local/MyCaseStudy/settings (see section 4.4). Be cautious if you have some custom modifications in your local files in /data/local/MyCaseStudy/settings: you may want to merge your changes into the updated configuration files.

4.7 Customizing the path of your installation

In case you need to change the layout of files and directories to customize your installation, set variables P4R_ENV, PYTHONSCRIPTS and DATA variables to the corresponding <u>absolute</u> path in your custom installation.
